Abstract The Three Gorges Dam in the upper Yangtze River in China is the largest hydropower project in the world. Length- weight relationships (LWRs) are reported for fish species collected from three locations of the reservoir from November 2010 to October 2011. Fish were collected from the local fishing boats using 1.5 cm nylon mesh trap nets or 4, 5 and 6 cm nylon mesh gillnets (100- 120 m long × 1.4-1.5 m high). A total of 7,311 fish representing 49 species of 11 families were collected during the study period. There were 2,680 fish belonging to 32 species of 8 families sampled in Zigui (near the dam) reach, 2,845 fish representing 46 species of 8 families in Wanzhou (middle of the reservoir) reach and 1,786 fishes representing 38 species of 8 families in Fuling (upper reservoir) reach. The family with the highest number of species was Xenocypridae. The intercept (a) and slope (b) of LWRs are useful in fisheries science in many ways. Therefore, the present study provides baseline data on LWRs of the economically valuable and most abundant fish species in the recently commissioned Three Gorges Reservoir.

Keywords: Allometric growth, Freshwater fish, Hydropower reservoir, Isometric growth**INTRODUCTION**

The Three Gorges Reservoir (TGR) in the upper Yangtze River is the largest hydropower scheme in the world (Kittinger et al. 2009; Yang et al. 2011). Although there are economic and social benefits to the society through construction of dams and reservoirs, they bring about some impacts on the riparian habitats (Poff and Hart 2002; Poff et al. 2007). Therefore, the effects of dams on riverine fish species have been of great concern today (Baxter 1977; Greathouse et al. 2006). Some researchers have shown changes in both fish assemblage structure and their diversity with the impoundment (Wu et al. 2004; Agostinho et al. 2008). The effects of river impoundments on fish

assemblage structure at downstream portions have been widely investigated (Taylor et al. 2014), but less in upstream changes (Franseen and Tobler 2013).

The length (L) - weight (W) relationship (LWR) of fish can be estimated using equation, $W = a L^b$, where a and b are constants, and the growth and condition of the fish are known to be influenced by several factors such as season, food, temperature and physical activity (Pauly 1983; Petrakis and Stergiou 1995; Froese 2006). The LWR of the fish is important in the biological studies of the fish, their stock assessment and estimation of biomass from length measurements (Krause et al. 1998; Valle et al. 2003; Offem et al. 2009). LWRs of fish provide information on the condition of fish, their

growth pattern and comparative life histories of fish species between regions. They are useful to elucidate the possible differences between separate unit stocks of the same species indicating the wellbeing of the species (Le Cren 1951; Kumolu-Johnson and Nadimele 2011). The constants (a and b) of LWRs are useful in fisheries science in many ways including comparison of life history and morphology of fish populations (Petraakis and Stergiou 1995). Fish are poikilothermic animals that live permanently in water so that their metabolic activities are directly affected by changes in the ambient temperature of the habitat (Parrish and Mallicoate 1995). Some studies have shown LWRs of the fish species in the TGR collected using different fishing gears (Chen et al. 2016; Wei et al. 2019). However, the information on the LWR of fish species along the TGR after impoundment is scanty. Therefore, the present study attempts to provide baseline data on LWRs of economically valuable and most abundant fish species collected from three reaches of the upper Yangtze River of the TGR.

MATERIALS AND METHODS

Fish sampling was monthly carried out in three areas of the TGR in the main stream of the upper Yangtze River from November 2010 to October 2011, Zigui reach (near the dam, about 1.9 km from the dam) (30°51' N, 111°00' E), Wanzhou reach (middle reservoir, about 300 km up of the dam) (30°49' N, 108°23' E) and Fuling reach (upper reservoir, about 500 km away from the dam) (29°42' N, 107°23' E) (Figure. 1). Monthly sampling was carried out for 8-10 days and during each sampling visit, 5-8 fishing boats (40-50% boats) were selected for sampling fish. Fish were collected from the local fishing boats using 1.5 cm nylon mesh trap nets or 4, 5 and 6 cm nylon mesh gillnets (100- 120 m long × 1.4-1.5 m high). Fish samples collected from fishers were placed in ice and transported to the laboratory and samples were frozen at -20°C and stored until analyses. The specimens were sorted and identified. The total length (TL) of each fish was measured from the tip of the snout to the longest caudal- fin ray to the nearest 0.1 cm. Weight (W in g) of the fish was recorded on an electric balance sensitive to 0.001g, after blot-drying excess water from the body.

Statistical analysis

Using linear regression analysis, the relationships between TL and W of each fish species were determined for \log_{10} transformed data in the three sampling regions of the reservoir separately. The log transformed relationship was $\log W = \log a + b \log L$, where W is the body weight (in g), L is the total length (in cm), $\log a$ is the intercept of the regression and b is the slope. All the statistical analyses were considered as significant at 5% probability ($p < 0.05$). All statistical analyses were performed using SPSS 16.0 software.

RESULTS

A total of 7,311 fish representing 49 species of 11 families were collected during the study period. There were 2,680 fish belonging to 32 species of 8 families sampled in Zigui (near the dam) reach. 2,845 fish representing 46 species of 8 families in Wanzhou (middle of the reservoir) reach and 1,786 fishes representing 38 species of 8 families in Fuling (upper reservoir) were collected. The family with the higher number of species was Xenocypridae (Table 1). Sample descriptive statistics and estimated parameters of the LWR for Zigui, Wanzhou and Fuling sites are summarized in Tables 2, 3 and 4 respectively. In Zigui, the sample size ranged from 41 for *Hypophthalmichthys molitrix* to 621 for *Hemiculter bleekeri*. The sample size in Wanzhou ranged from 57 for *Leiocassis longirostris* and 509 for *Hemiculter bleekeri*. In Fuling, the sample size ranged from 51 for *Rhinogobio cylindricus* to 183 for *Saurogobio dabryi*.

DISCUSSION

The length-weight relationship (LWR) is an important factor in the biological study of fishes and their stock assessment and it describes the important information on growth patterns and growth rates of fish. Further, it describes the functional regime in the weight distribution of a sub population (Morato et al. 2001). The fish grows isometrically when the b equal 3 (Rahim et al. 2009) and when the b value was different from 3, it shows the negative or positive allometric growth pattern (Amin et al. 2008). Mainly the b values depend on both the shape and fatness of the species. Chen et al. (2016) reported LWRs of 55 fish species in the TGR. The LWRs of nine fish species collected from the TGR were given by Gong et al. (2018). The LWRs of 15 fish species in the three reaches (lower, middle and upper) from the TGR were reported by Wei et al. (2019). In this study, LWRs of the economically valuable and most abundant fish were presented. Because of the ecological and economic importance of these species and also as this reservoir has been recently filled, the data on their functional LWR might be important when studying growth and population parameters.

CONCLUSION

The present study provides baseline data on LWRs of the economically valuable and most abundant fish species in the recently completed TGR. The relationships presented from in this study can be used in studying growth and population studies of the fish in TGR.
